## MC33030

## DC Servo Motor Controller/Driver

The MC33030 is a monolithic DC servo motor controller providing all active functions necessary for a complete closed loop system. This device consists of an on-chip op amp and window comparator with wide input common-mode range, drive and brake logic with direction memory, Power $\mathrm{H}-$ Switch driver capable of 1.0 A , independently programmable over-current monitor and shutdown delay, and over-voltage monitor. This part is ideally suited for almost any servo positioning application that requires sensing of temperature, pressure, light, magnetic flux, or any other means that can be converted to a voltage.

Although this device is primarily intended for servo applications, it can be used as a switchmode motor controller.

- On-Chip Error Amp for Feedback Monitoring
- Window Detector with Deadband and Self Centering

Reference Input

- Drive/Brake Logic with Direction Memory
- 1.0 A Power H-Switch
- Programmable Over-Current Detector
- Programmable Over-Current Shutdown Delay
- Over-Voltage Shutdown

This device contains 119 active transistors.

The MC33030 was designed to drive fractional horsepower DC motors and sense actuator position by voltage feedback. A typical servo application and representative internal block diagram are shown in Figure 17. The system operates by setting a voltage on the reference input of the Window Detector (Pin 1) which appears on (Pin 2). A DC motor then drives a position sensor, usually a potentiometer driven by a gear box, in a corrective fashion so that a voltage proportional to position is present at Pin 3. The servo motor will continue to run until the voltage at Pin 3 falls within the dead zone, which is centered about the reference voltage.

The Window Detector is composed of two comparators, A and B , each containing hysteresis. The reference input, common to both comparators, is pre-biased at $1 / 2 \mathrm{~V}$ CC for simple two position servo systems and can easily be overridden by an external voltage divider. The feedback voltage present at Pin 3 is connected to the center of two resistors that are driven by an equal magnitude current source and sink. This generates an offset voltage at the input of each comparator which is centered about Pin 3 that can float virtually from $\mathrm{V}_{\mathrm{CC}}$ to ground. The sum of the upper and lower offset voltages is defined as the window detector input dead zone range.

To increase system flexibility, an on-chip Error Amp is provided. It can be used to buffer and/or gain-up the actuator position voltage which has the effect of narrowing the dead zone range. A PNP differential input stage is provided so that the input common-mode voltage range will include ground. The main design goal of the error amp output stage was to be able to drive the window detector input. It typically can source 1.8 mA and sink $250 \mu \mathrm{~A}$. Special design considerations must be made if it is to be used for other applications.

The Power H-Switch provides a direct means for motor drive and braking with a maximum source, sink, and brake current of 1.0 A continuous. Maximum package power dissipation limits must be observed. Refer to Figure 15 for thermal information. For greater drive current requirements, a method for buffering that maintains all the system features is shown in Figure 30.

The Over-Current Monitor is designed to distinguish between motor start-up or locked rotor conditions that can occur when the actuator has reached its travel limit. A fraction of the Power H -Switch source current is internally fed into one of the two inverting inputs of the current comparator, while the non-inverting input is driven by a programmable current reference. This reference level is controlled by the resistance value selected for ROC, and must be greater than the required motor run-current with its
mechanical load over temperature; refer to Figure 8. During an over-current condition, the comparator will turn off and allow the current source to charge the delay capacitor, CDLYWhen CDLY charges to a level of 7.5 V , the set input of the over-current latch will go high, disabling the drive and brake functions of the Power H-Switch. The programmable time delay is determined by the capacitance value-selected for CDLY.

This system allows the Power H-Switch to supply motor start-up current for a predetermined amount of time. If the rotor is locked, the system will time-out and shut-down. This feature eliminates the need for servo end-of-travel or limit switches. Care must be taken so as not to select too large of a capacitance value for CDLY. An over-current condition for an excessively long time-out period can cause the integrated circuit to overheat and eventually fail. Again, the maximum package power dissipation limits must be observed. The over-current latch is reset upon power-up or by readjusting VPin 2 as to cause VPin 3 to enter or pass through the dead zone. This can be achieved by requesting the motor to reverse direction.

An Over-Voltage Monitor circuit provides protection for the integrated circuit and motor by disabling the Power H -Switch functions if $\mathrm{V}_{\mathrm{CC}}$ should exceed 18 V . Resumption of normal operation will commence when $\mathrm{V}_{\mathrm{CC}}$ falls below 17.4 V .

A timing diagram that depicts the operation of the Drive/Brake Logic section is shown in Figure 18. The waveforms grouped in [1] show a reference voltage that was preset, appearing on Pin 2, which corresponds to the desired actuator position. The true actuator position is represented by the voltage on Pin 3 . The points $\mathrm{V}_{1}$ through $\mathrm{V}_{4}$ represent the input voltage thresholds of comparators A and B that cause a change in their respective output state. They are defined as follows:
$\mathrm{V}_{1}=$ Comparator B turn-off threshold
$\mathrm{V}_{2}=$ Comparator A turn-on threshold
$\mathrm{V}_{3}=$ Comparator A turn-off threshold
$\mathrm{V}_{4}=$ Comparator B turn-on threshold
$\mathrm{V}_{1}-\mathrm{V}_{4}=$ Comparator B input hysteresis voltage
$\mathrm{V}_{2}-\mathrm{V}_{3}=$ Comparator A input hysteresis voltage
$\mathrm{V}_{2}-\mathrm{V}_{4}=$ Window detector input dead zone range
$\left|\left(\mathrm{V}_{2}-\mathrm{V}_{\text {Pin2 }}\right)-\left(\mathrm{V}_{\operatorname{Pin} 2}-\mathrm{V}_{4}\right)\right|=$ Window detector input voltage

It must be remembered that points $\mathrm{V}_{1}$ through $\mathrm{V}_{4}$ always try to follow and center about the reference voltage setting if it is within the input common-mode voltage range of Pin 3 ; Figures 4 and 5. Initially consider that the feedback input voltage level is somewhere on the dashed line between $\mathrm{V}_{2}$ and $\mathrm{V}_{4}$ in [1]. This is within the dead zone range as defined above and the motor will be off. Now if the reference voltage is raised so that $\mathrm{V}_{\operatorname{Pin} 3}$ is less than $\mathrm{V}_{4}$, comparator B will turn-on [3] enabling Q Drive, causing Drive Output A to sink and B to source motor current [8]. The actuator will move in Direction B until $\mathrm{V}_{\operatorname{Pin}} 3$ becomes greater than $\mathrm{V}_{1}$. Comparator B will turn-off, activating the brake enable [4]
and $\overline{\mathrm{Q}}$ Brake [6] causing Drive Output A to go high and B to go into a high impedance state. The inertia of the mechanical system will drive the motor as a generator creating a positive voltage on Pin 10 with respect to Pin 14 . The servo system can be stopped quickly, so as not to over-shoot through the dead zone range, by braking. This is accomplished by shorting the motor/generator terminals together. Brake current will flow into the diode at Drive Output B, through the internal $\mathrm{V}_{\mathrm{CC}}$ rail, and out the emitter of the sourcing transistor at Drive Output A. The end of the solid line and beginning of the dashed for $V_{\operatorname{Pin}} 3$ [1] indicates the possible resting position of the actuator after braking.

Figure 17. Representative Block Diagram and Typical Servo Application

If $V_{\operatorname{Pin}} 3$ should continue to rise and become greater than $\mathrm{V}_{2}$, the actuator will have over shot the dead zone range and cause the motor to run in Direction A until $V_{P i n} 3$ is equal to $\mathrm{V}_{3}$. The Drive/Brake behavior for Direction A is identical to that of $B$. Overshooting the dead zone range in both directions can cause the servo system to continuously hunt or oscillate. Notice that the last motor run-direction is stored in the direction latch. This information is needed to determine whether Q or $\overline{\mathrm{Q}}$ Brake is to be enabled when VPin 3 enters the dead zone range. The dashed lines in [8,9] indicate the resulting waveforms of an over-current condition that has exceeded the programmed time delay. Notice that both Drive Outputs go into a high impedance state until VPin 2 is readjusted so that VPin 3 enters or crosses through the dead zone [7, 4].

The inputs of the Error Amp and Window Detector can be susceptible to the noise created by the brushes of the DC motor and cause the servo to hunt. Therefore, each of these inputs are provided with an internal series resistor and are pinned out for an external bypass capacitor. It has been found that placing a capacitor with short leads directly across the brushes will significantly reduce noise problems. Good quality RF bypass capacitors in the range of 0.001 to $0.1 \mu \mathrm{~F}$ may be required. Many of the more economical motors will generate significant levels of RF energy over a spectrum that extends from DC to beyond 200 MHz . The capacitance value and method of noise filtering must be determined on a system by system basis.

Thus far, the operating description has been limited to servo systems in which the motor mechanically drives a potentiometer for position sensing. Figures 19, 20, 27, and 31 show examples that use light, magnetic flux, temperature, and pressure as a means to drive the feedback element. Figures 21, 22 and 23 are examples of two position, open loop servo systems. In these systems, the motor runs the actuator to each end of its travel limit where the Over-Current Monitor detects a locked rotor condition and shuts down the drive. Figures 32 and 33 show two possible methods of using the MC33030 as a switching motor controller. In each example a fixed reference voltage is applied to Pin 2. This causes $\mathrm{V}_{\text {pin }} 3$ to be less than $\mathrm{V}_{4}$ and Drive Output A, Pin 14, to be in a low state saturating the TIP42 transistor. In Figure 32, the motor drives a tachometer that generates an ac voltage proportional to RPM. This voltage is rectified, filtered, divided down by the speed set potentiometer, and applied to Pin. 8. The motor will accelerate until $\mathrm{V}_{\text {Pin }} 3$ is equal to $\mathrm{V}_{1}$ at which time Pin 14 will go to a high state and terminate the motor drive. The motor will now coast until $V_{\text {Pin }} 3$ is less than $V_{4}$ where upon drive is then reapplied. The system operation of Figure 31 is identical to that of 32 except the signal at Pin 3 is an amplified average of the motors drive and back EMF voltages. Both systems exhibit excellent control of RPM with variations of $\mathrm{V}_{\mathrm{CC}}$; however, Figure 32 has somewhat better torque characteristics at low RPM.

ON Semiconductor and are trademarks of Semiconductor Components Industries, LLC (SCILLC). SCILLC reserves the right to make changes without further notice to any products herein. SCILLC makes no warranty, representation or guarantee regarding the suitability of its products for any particular purpose, nor does SCILLC assume any liability arising out of the application or use of any product or circuit, and specifically disclaims any and all liability, including without limitation special, consequential or incidental damages. "Typical" parameters which may be provided in SCILLC data sheets and/or specifications can and do vary in different applications and actual performance may vary over time. All operating parameters, including "Typicals" must be validated for each customer application by customer's technical experts. SCILLC does not convey any license under its patent rights nor the rights of others. SCILLC products are not designed, intended, or authorized for use as components in systems intended for surgical implant into the body, or other applications intended to support or sustain life, or for any other application in which the failure of the SCILLC product could create a situation where personal injury or death may occur. Should Buyer purchase or use SCILLC products for any such unintended or unauthorized application, Buyer shall indemnify and hold SCILLC and its officers, employees, subsidiaries, affiliates, and distributors harmless against all claims, costs, damages, and expenses, and reasonable attorney fees arising out of, directly or indirectly, any claim of personal injury or death associated with such unintended or unauthorized use, even if such claim alleges that SCILLC was negligent regarding the design or manufacture of the part. SCILLC is an Equal Opportunity/Affirmative Action Employer.
